Test Date: March 31st, 2026

Customer-supplied information

Owner Name: Melvin Lapp
Dog Name: Sugar
Sex: Female
Date of birth: 01/18/25

Breed type: N/A
Breed: Bernese Mountain Dog
Breed registration: N/A
Microchip: N/A

Genetic summary

Genetic breed identification:
Bernese Mountain Dog

Breed ancestry:

Bernese Mountain Dog: 100.0%

Predicted adult weight: **82 lbs**
Calculated from 17 size genes.

Life stage: **Young adult**
Based on date of birth provided.

Health Report

How to interpret Sugar's genetic health results:

If Sugar inherited any of the variants that we tested, they will be listed at the top of the Health Report section, along with a description of how to interpret this result. We also include all of the variants that we tested Sugar for that we did not detect the risk variant for.

A genetic test is not a diagnosis

This genetic test does not diagnose a disease. Please talk to your vet about your dog's genetic results, or if you think that your pet may have a health condition or disease.

Summary

Of the 274 genetic health risks we analyzed, we found 1 result that you should learn about.

Health Report

BREED-RELEVANT RESULTS

Research studies indicate that these results are more relevant to dogs like Sugar, and may influence her chances of developing certain health conditions.

Degenerative Myelopathy, DM (SOD1A)	Clear
Von Willebrand Disease Type I, Type I vWD (VWF)	Clear

Health Report

OTHER RESULTS

Research has not yet linked these conditions to dogs with similar breeds to Sugar. Review any increased risk or notable results to understand her potential risk and recommendations.

Mast Cell Tumor	Increased risk
2-DHA Kidney & Bladder Stones (APRT)	Clear
Acral Mutilation Syndrome (GDNF-AS, Spaniel and Pointer Variant)	Clear

Increased risk result

Mast Cell Tumor

Sugar's genetic results are associated with an increased risk of developing a mast cell tumor.

What does this mean for Sugar?
An estimated 96 out of 1,000 female dogs with genetics and breed ancestry similar to Sugar have received a mast cell tumor diagnosis. Among dogs without any of those common genetic factors, approximately 37 out of 1,000 female dogs have received a mast cell tumor diagnosis. The results were calculated using genetic results plus diagnoses provided in Embark surveys, and may continue to be refined over time as we collect more data.

What can you do?
The good news is this type of cancer is usually easy to diagnose and very treatable if detected early. Understanding the signs and when to seek care for a health condition can help you prepare for any outcome.

We recommend the following:

1. **Take a deep breath (and pet your dog!)**
   We know it can be concerning to learn of an increased health risk for your dog. Remember, this test result is not a diagnosis; it is an assessment of risk and does not guarantee that a dog will or will not develop a disease. You can use this information to make informed, proactive decisions for your dog's health.
2. **Take action**
   Petting your dog is a great way to take action. Start incorporating body checks into your dog's routine by laying your hand flat against their body to feel for any masses on, under, or within the skin. Make an appointment with your veterinarian as soon as possible if you notice any new masses or ones that have changed size, color, or hair cover, or are bleeding.
3. **Consult with your veterinarian**
   Consult with your vet so you can make a plan to monitor your dog’s health. If your dog is diagnosed with this condition, your veterinarian will help you determine which medical or surgical intervention options are best for your dog.

Risk Factors
Embark’s risk model is based on breed ancestry, the dog’s sex, and certain genetic markers associated with MCTs. The exact cause of MCTs may be due to a variety of genetic and environmental factors. Any breed or breed-mix can develop MCTs, but certain breeds are more susceptible such as the American Pit Bull Terrier, Boston Terrier, and Boxer.

Clinical Signs
Dogs with MCTs may exhibit any combination of the following signs:

- a new mass under or within the skin
- an existing mass that has changed size, color, or hair cover
- swelling, redness, and/or itching of an existing mass
- a bleeding mass
- swelling of the face or hives
- a mass that gets bigger then smaller over a 24-hour period
- unexplained loss of appetite, vomiting, and/or diarrhea

It is important to make an appointment with your veterinarian as soon as possible if you notice any of the above signs, or if an undiagnosed mass grows greater than 1 cm (about the size of a pea). Because MCTs can itch and be irritating, dogs may bite, lick, or scratch at the tumor causing mast cells to release their contents, including histamine. Having your dog wear an E-collar (Elizabethan collar) until your veterinary appointment may be necessary to prevent the dog from aggravating the tumor.

Diagnosis

MCTs can be accurately diagnosed with a fine needle aspirate of the tumor in almost all cases. Any breed or breed-mix can get MCTs, but certain breeds are more susceptible such as the American Pit Bull Terrier, Boston Terrier, and Boxer.

Your veterinarian may recommend additional tests for your dog, including a fine needle aspiration of the lymph nodes and abdominal organs, to determine if the tumor cells have spread. Other tests like bloodwork and urinalysis may also be used to check for the secondary effects of the spread of cancerous cells or your dog's ability to tolerate different treatment options. A tissue sample is needed from the tumor to determine its grade, which helps in the prognosis and with treatment options.

Treatment

Surgical removal of MCTs is the preferred treatment, although your veterinarian can recommend the best course of action for your individual dog. MCTs invade surrounding tissues like tentacles, and wide surgical margins (a wide area of healthy tissue surrounding the tumor) are necessary to remove all cancerous cells. The amount of normal tissue considered "wide" will be determined by your veterinarian taking into account clinical presentation, tumor location, and tumor grade (if known). Occasionally, additional or alternative treatment options may be suggested by your veterinarian. See related resources below to learn more.

Understanding ancestry-based risk

Certain diseases are more common in some breeds than others but without detailed genetic ancestry data, most research has only been able to focus on purebred dogs. Using breed ancestry data, we have developed a new approach for calculating risk in both single and mixed breed dogs.

To calculate a dog's ancestry-based risk, we start by comparing breed ancestry data and specific health conditions reported by owners in our surveys. To see if the data suggest an underlying genetic predisposition, we calculate how often the disease occurs among dogs with varying percentages of a specific breed compared to dogs without any of that breed or closely related breeds. Removing closely related breeds allows us to detect more clearly if there are any pronounced links between breed ancestry and disease.

Once we have identified that a certain breed appears to be disproportionately at risk for a health condition, we conduct genome-wide association studies to try to find genetic variants that are shared by dogs with the disease. We then combine ancestry percentage and genetic variant data with additional information that may influence the probability of disease (such as sex and body weight) to develop an algorithm that estimates an individualized risk score for a dog.

Ancestry-based risk models are a completely novel approach for predicting disease, powered by Embark Research and customers like you. These algorithms are based on data that our customers provide to us and will continue to improve over time as we collect more, so you may see slight updates to a dog's risk score.

Note that this is not a diagnostic test, and an increased risk result does not mean a dog will develop a MCT—nor that dogs without this result are free from risk. The results are intended to help you better monitor your dog for signs that can aid in early detection and improved treatment outcomes.

For breeders, using ancestry-based risk estimates when planning a litter is not recommended because it represents only a small fraction of risk within a breed and there are more genetic and non-genetic risk factors that our current algorithm cannot capture.

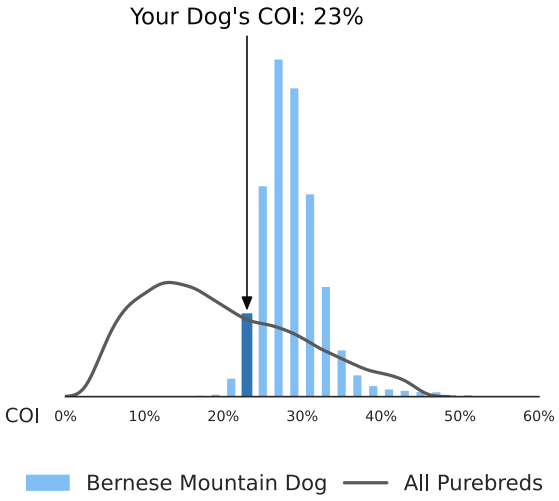
Genetic Diversity and Inbreeding

Coefficient of Inbreeding (COI)

Genetic Result: 23%

Our genetic COI measures the proportion of your dog's genome (her genes) where the genes on the mother's side are identical by descent to those on the father's side. The higher your dog's coefficient of inbreeding (the percentage), the more inbred your dog is.

Your Dog's COI



This graph represents where your dog's inbreeding levels fall on a scale compared to both dogs with a similar breed makeup to her (the blue bars) and all purebred dogs (the grey line).

Genetic Diversity and Inbreeding

More on the Science

Embark scientists, along with our research partners at Cornell University, have shown the impact of inbreeding on longevity and fertility and developed a state-of-the-art, peer-reviewed method for accurately measuring COI and predicting average COI in litters.

About Embark

Embark Veterinary is a canine genetics company offering research-grade genetic tests to pet owners and breeders. Every Embark test examines thousands of genetic markers, and provides results for over NaN genetic health conditions, breed identification, clinical tools, and more.

Embark is a research partner of the Cornell University College of Veterinary Medicine and collaborates with scientists and registries to accelerate genetic research in canine health. We make it easy for customers and vets to understand, share and make use of their dog's unique genetic profile to improve canine health and happiness.
